# From Pragmatic to Sentimental Adoption? Child Adoption in the United States, 1880-1930 

Chiaki Moriguchi<br>Northwestern University and NBER

Preliminary and Incomplete*
February 25, 2009

#### Abstract

Adoption, as an alternative to childbearing, is a widely accepted means of creating a family in the U.S. today. According to the historical literature, a modern form of adoption was a legal innovation in the mid-19th century that evolved over time and had profound implications for the welfare of adopted children and adoptive parents. Due to the lack of quantitative data, however, we know little about the extent and nature of adoption in the U.S. before WWII. How widely was adoption practiced before its widespread social acceptance? Who adopted children, and what motivated them to adopt? How did adopted children fare compared to biological children? In this paper, using microdata from the federal censuses in 1880-1930 and 2000, I document the prevalence of adoption and study the characteristics of adoptive children and their households. Among other things, I re-evaluate the commonly held hypothesis that, during the early 20th century, adoption evolved from "pragmatic" to "sentimental" adoption as adoptive parents began to demand children not for their potential labor value but for the utility of parenting itself. This paper provides the first empirical analysis of adoption in the pre-WWII U.S. using nationally representative data.

[^0]
## 1. Motivation

Adoption, as an alternative to childbearing, is a widely accepted means of forming a family in many western societies. In the United States, over 120,000 children are adopted every year. Although there are no definitive data, the U.S. likely adopts more children per capita than any other countries in the world (Bernal et al. (2007)). But even in America, it was not until the 1940s that adoption gained cultural and moral legitimacy. Indeed, recent work by social and cultural historians, such as Carp (1998, 2002), Berebitsky (2000), and Melosh (2002), reveals complex dynamics that changed the societal view of adoption over the last two centuries. By facilitating a permanent transfer of parental rights and duties from biological to adoptive parents, adoption has profound implications for the welfare of adopted children, adoptive parents, and relinquishing parents. How common was the practice of adoption in the U.S. before its widespread social acceptance? Who adopted children, and for what purposes did they adopt? Were adoptive families better off compared to biological families? More generally, the history of adoption should illuminate how the value of child, the utility of parenting, and the definition of family changed as the U.S. went through extraordinary social and economic transformation over the 20th century.

A major difficulty in studying adoption in the past, however, is the lack of data. Scholars have so far relied exclusively on case records of selective child welfare agencies or adoption agencies, contemporary accounts in magazines, newspapers, and letters, and occasional government publications. Quantitative data are exceedingly rare. National statistics on adoption simply do not exist before 1944 (Maza (1984)). The primary purpose of this paper is to construct a new dataset of adopted children using U.S. federal census microdata in 1880-1930 to study adoption before it became well-established practice. I also use 2000 census microdata to provide a modern benchmark for the historical data. The paper provides the first empirical analysis of adoption in the U.S. before WWII using nationally representative data. Because the 1880-1930 data period coincides with a critical period of transition as I describe below, this paper offers particularly valuable new evidence to the historical literature.

## 2. Historical Background, 1850-1950

During the 19 th century, adoption was seen primarily as a means to save orphaned or abandoned children by providing them a better, permanent home. As most dramatically showcased in the "orphan train movement," between 1854 and 1894 , over 84,000 homeless children in New York City were transported by railroads and placed in rural homes most notably in the Midwest (Holt (1992), p.53). ${ }^{1}$ Most families took them in as potential farm laborers or housekeepers while agreeing to provide proper

[^1]care and schooling. ${ }^{2}$ Early demand for adoption was thus allegedly driven by a combination of needs for labor and a sense of fulfilling moral duty in saving destitute children. Older children (age 12 to 15), especially boys, were often placed under indenture contracts, while younger children were more likely to be "adopted". In reality, however, a majority of these children were not formally adopted for three main reasons. First, in many states, there was no statute that allowed legal creation of parent-child relations. The first adoption law that enabled permanent transfer of parental rights was enacted in Massachusetts in 1851, and 24 states passed similar laws by 1880 (Carp (2000), p.6). Second, despite the name, many "orphan train" children were not orphans but had at least one living parent, which made formal adoption difficult even in the presence of the law. Third, some families chose not to adopt legally because the process could be formidable and costly or inheritance rights didn't matter much for them (Berebitsky (2000), pp.40-41). ${ }^{3}$ In other words, in the late 19 th century, adoption was often informally practiced, and there was no clear distinction between fostering and adopting a child (Herman (2007)). Historical studies suggest that, throughout the 19th century, adopting an unrelated infant and raising the child "as their own" remained uncommon due to both hereditary concerns and high infant mortality. As adoption was motivated mainly by practical needs or altruism to help children, adoptive parents were reportedly varied and diverse, including single, divorced, or widowed women, older couples, and couples with biological children (Berebitsky (2000), p.3).

According to the literature, towards the end of the 19th century, parents in general began to value children for reasons more emotional than economic (Berebitsky (2000), pp.21-22). Labor value of children declined dramatically from 1880 to 1930, as indicated by a fall in child labor force participation rates, a rise in secondary school enrollment rates, and an increasing number of states passing child labor laws and compulsory schooling laws (Moehling (1999) and Goldin and Katz (2008)). Reflecting these changes, adoption, too, evolved from "pragmatic" to "sentimental" adoption in which parents adopted a child for completing a family and experiencing parenthood itself. With a growing perception that nurture could be more important than nature, the number of childless couples requesting for an infant, often with a preference for a girl, began to rise. The major improvements in infant formula in the 1920s that enabled the adoption of young infants further increased the demand for adoption. ${ }^{4}$ At the same time, child welfare reform in the Progressive Era (1900-1918) led to the

[^2]establishment of adoption agencies staffed with professional social workers and greater state oversight (Carp (2000), p.7). On the supply side, until the 1920s social workers generally pressed unwed mothers to keep their children, and it was only in the 1930s that they began counseling mothers to relinquish out-of-wedlock babies (Askeland (2006), p.34). Anecdotal evidence indicates that the demand for adoptable infants began to exceed the supply for the first time around the 1920s and 1930s (Gill (2002), p.175; Carpe (2002), p.160). As adoption agencies screened applicants using increasingly strict standards and elaborate matching criteria, the characteristics of adoptive parents shifted towards married couples with higher socioeconomic status and no biological children (Carpe (2002), p.202). ${ }^{5}$ It was only in the late 1940s that professional agencies began to charge fees for adoption placements (Berebitsky (2000), p.5). Disqualified prospective parents often turned to independent arrangements through doctors or lawyers without involving any agencies (Pfeffer (2002), pp.111-2). To protect the welfare of children, between 1917 and 1941, 34 states enacted new adoption laws that mandated a social investigation of prospective adoptive parents prior to court approval (Schapiro (1956), p.18). [Also provide a brief history of the foster care system.]

In summary, according to the historical literature, the practice of adoption in the U.S. underwent a profound shift from the 1850s to the 1930s. In terms of legal innovations, the diffusion of adoption laws after 1851 enabled adoptive parents to establish their parental rights permanently, and the revised laws provided greater state oversight and better protection of adopted children from potential abuse. In terms of demand and supply, during most of the 1880-1930 period, there was an excess supply of children at all ages looking for adoptive homes. It was not until the 1920s that the demand for adoptable healthy infants began to surpass its supply. In terms of parental motives, it had evolved from "altruistic" adoption, in which parents adopted orphaned or abandoned children to provide better home, and "pragmatic" adoption, in which parents took in unrelated children to their homes primarily for their labor value, towards "sentimental" adoption in which adoptive parents adopted unrelated children to derive utility from parenting itself. The literature thus indicates substantial changes in the demographic and socioeconomic characteristics of adopted children and adoptive parents from the 1850s to the 1930s.

## 3. Data

The evolution of child adoption documented above is based primarily on detailed case studies of a handful of public child welfare agencies and private adoption agencies. Although these studies are enormously informative, their findings may not be representative and may suffer from potentially

[^3]serious selection bias. In fact, the evidence comes disproportionately from formal (i.e., legal) adoptions of unrelated children by white parents arranged through professional agencies. As a result, we have little data on independent adoption (adoption without involving any agencies), related adoption (adoption of children by relatives or stepparents), and informal adoption. Even more problematic, we know very little about adoption among blacks, not only because few public and private agencies served black families prior to the 1940s, but also because blacks were by tradition more likely to practice informal adoption (Carp (1998), pp.32-36; Askeland (2006), pp.10-13; Berebistaky (2000), pp.9-10).

In this paper, I compile a new dataset of adopted children using U.S. census data from the Integrated Public Use Microdata Series (IPUMS) in 1880, 1900, 1910, 1920, and 1930 (Ruggles et al. (2008)). Although it is widely assumed that adopted children were assigned an independent category for the first time in the 2000 census questionnaire, ${ }^{6}$ using detailed family relationship codes, one can identify adopted children separately from biological and step children in the 1880-1930 censuses. To my knowledge, these data have never been used for the purpose of studying adoption. The merits of using IPUMS data are multitude. First, it provides a nationally representative sample of U.S. population in every decade (except for 1890 for which census manuscripts were lost), and its sample size is large enough to contain 600 to 1,700 adopted children each year. ${ }^{7}$ Second, because family relationships are self-reported by the head of household, unlike court records or agency records, adoption in IPUM data is comprehensive and includes formal and informal adoption, agency and non-agency adoption, and unrelated and related adoption. Furthermore, IPUMS data contain rich demographic and socioeconomic information on every person residing in the same household (including not only family members but also co-resident nonrelatives such as servants). Lastly, the 2000 census data provide an ideal modern counterpoint to the historical data, which allows us to compare adoption practices in the U.S. across century. There are some major limitations, however. Most critically, we do not know children's age at adoption. Second, due to self reporting, trends in the data may reflect changes in the society's definition of adoption or household's willingness to identify adopted children. Lastly, we cannot distinguish unrelated adoption from related adoption. In particular, related adoption includes stepparent adoption, and in recent years, as much as $40 \%$ of legal adoption are stepparent adoption (Bernal et al. (2007), p.8). This creates a serious problem in the 2000 data. Fortunately, as I discuss later, this problem seems to be minor in the 1880-1930 data.

[^4]
## 4. Trends in Descriptive Statistics

### 4.1. Prevalence of Child Adoption, 1880-1930 \& 2000

How common was adoption in the late 19th century? Did adoption become more popular in the early 20th century in response to less stigma and wider social acceptance? Table 1 reports the estimated numbers of biological, adopted, step, and foster children in U.S. households in 1880-1930 and 2000. Alaska and Hawaii are excluded from all years to maintain consistency across years. Although I include Native Americans and Asians in the table, due to small sample size, estimates for these races are unreliable in early census years. Throughout this paper, child is defined as any person under age 18 (age 0 to 17) residing in a household whose relationship to the household head is reported as "child," including biological, step, and adopted children. I also include foster children in the table even though foster child is reported (not as "child" but) as co-resident nonrelatives in IPUMS. ${ }^{8}$ It must be noted that the child type is always defined in relation to household head, while the relationship between a child and a spouse of the household head is not directly identified. For example, consider the case of married two-parent households with children. In 1880-1930, in virtually all such households the household head is children's father and not mother. In these households, children are labeled "biological" if they have a biological father, regardless of their relationship to a mother. Thus, in our definition, biological children include not only children who have two birth parents but also those who have a biological father and a stepmother. Similarly, children are labeled "adopted" when they have an adoptive father even if their mother is a biological or step mother. As a result, adopted children in our definition include adopted stepchildren (as in the case of a remarried husband adopting his wife's biological children from her previous marriage). ${ }^{9}$ Accordingly, step children in our definition exclude children of a biological father and a stepmother. Because our definitions of biological and adopted children overlap with "stepchildren" in its common usage of the term, for comparison, I keep step children (in our definition) as a child type throughout the paper.

According to Table 1, in 1880-1930, on average $0.26 \%$ of white children under age 18 in all households were adopted, compared to $2.2 \%$ in 2000 . Although $0.26 \%$ may seem small, given the fact that even in 2000 when adoption seems ubiquitous the adopted children were only $2 \%$ of all children, it shows that adoption was surprisingly common in the earlier period. I find, however, no positive trend in the share of adopted children from 1880 to 1930 among whites. This could be that the literature's emphasis on a rising demand for agency adoption has been misplaced or that such increase was offset

[^5]by a decline in other types of adoption. By contrast, for black children, the percentage of adopted children in all children rose from $0.40 \%$ in 1880 to $0.97 \%$ in 1930 except for a drop in 1920. For all years, adoption was more common among blacks than whites, and the difference grew between 1880 and 1930. In 2000, however, black children were only slightly more likely to be adopted children than the white counterparts ( $2.2 \%$ versus $2.8 \%$ ). Although the data are limited, virtually all Asian children were biological children of the household head in 1880-1930. By contrast, $5.1 \%$ of Asian children in 2000 were adopted children due to a large number of international adoption from China, Korea, and Vietnam in recent decades (Bernal et al. (2007), pp.13-14). ${ }^{10}$ With respect to step children, due to low divorce rates, they historically constituted much lower percentage of all children than today for whites (less than $1.5 \%$ in $1880-1930$ versus $5.3 \%$ in 2000) and somewhat lower percentage for blacks (around $3 \%$ in $1880-1930$ versus $4.5 \%$ in 2000). Finally, compared to 2000 , foster children constituted a very small share (less than $0.1 \%$ ) in 1880-1930 for both whites and blacks. This is largely due to the absence of state-subsidized paid foster care prior to the 1930s, although some child welare agencies paid board to foster parents as early as in the 1890s (Askeland (2006), p.33; Berebitsky (2000), p.181).

### 4.2. Marital Status of Adoptive Parents, 1880-1930 \& 2000

To explore if adoptive parents became less diverse a population from 1880 to 1930, in Table 2, I classify biological, adopted, step, and foster children by the marital status of their household head. Because the unit of observation is child, a household with multiple children is counted multiple times in the statistics. Due to sample size, the results are reported only for white and black children in 18801930 and for white, black, and Asian children in 2000. Several important observations follow. First, for biological children, throughout 1880-1930, over $90 \%$ of white children and over $80 \%$ of black children lived in a married two-parent ("married, spouse present") household. Although the share of biological children living in a divorced single-parent household climbed from $0.15 \%$ to $0.55 \%$ for whites and from $0.48 \%$ to $1.0 \%$ for blacks in $1880-1930$, these numbers are extremely low compared to $10.5 \%$ for whites and $13.3 \%$ for blacks in 2000 . By contrast, the share of biological children living in a widowed single-parent household in 1880-1930 (5-7\% for whites and 10-12\% for blacks) was substantially higher than the 2000 counterpart ( $1.0 \%$ for whites and $1.8 \%$ for blacks), reflecting higher mortality rates in the earlier period. In other words, unlike in 2000, step children in 1880-1930 were primarily a consequence of parental death as opposed to divorce. Second, the percentage of biological children living in a household with a never-married parent is less that $0.2 \%$ for whites and $1-3 \%$ for blacks in 1880-1930, compared to $5.3 \%$ for whites and astounding $33.4 \%$ for blacks in 2000 . The dramatically

[^6]smaller numbers in 1880-1930 indicate strong social stigma against unwed mothers and out-of-wedlock children before WWII for both races.

Third, turning to adopted children, as the literature suggests, adoptive parents were more diverse than biological parents in 1880-1930. There is no clear evidence, however, that their heterogeneity declined towards 1930. Compared to biological children, for both races, adopted children were consistently less likely to live in a married two-parent households, more likely to live in a widowed single-parent household, and much more likely to live in a household with a never-married parent. ${ }^{11}$ (For blacks, the differences are not always statistically significant due to smaller sample sizes.) This may suggest that adoption was relatively common among the never-married and the widowed, or alternatively, older couples were more likely to adopt who were also more likely to become widowed before their adopted children reach age 18. By sharp contrast, in 2000, reflecting adoption agencies' preferences for married couples, adopted children were more likely to live in a married two-parent household and less likely to live in a never-married household compared to biological children. Fourth, as we expect, for both races, almost all step children resided in a (re)married two-parent household in 1880-1930. They were much less likely to live in a widowed household than biological children, because step children are by definition considerably older and thus less likely to experience the death of (another) parent before they reach age 18. In 2000, too, most step children lived in a married two-parent household. ${ }^{12}$ Finally, small sample sizes notwithstanding, compared to biological children, foster children were much less likely to live with two married parents and more likely to live with a widowed or never-married parent in 1880-1930. These trends are similar or even more pronounced in 2000. It is reassuring to note that, given that adopted children and foster children were not well distinguished in the earlier period, they exhibit similar characteristics in Table 2. It is also important to note that adopted children and step children consistently exhibit opposite characteristics in 1880-1930, which suggests that these two types of children are well differentiated in the historical data with no major presence of adopted stepchildren. This is not the case in 2000 where up to $40 \%$ of adopted children could be adopted stepchildren.

### 4.3. Composition of Children in Adoptive Households, 1880-1930 \& 2000

Because the marital status of household head is highly correlated with child types, to keep our sample more homogenous across years, from now on, I focus on married two-parent households with at least one biological, adopted, or step child under age 18 (and drop all singe-parent households). Switching

[^7]from child-level observations to household-level observations, in Table 3, I classify these households by the mix of child types within household. The race of household is defined by the race of household head. ${ }^{13}$ According to Table 3, in 1880-1930, about $97 \%$ of (married two-parent) households (with children) had only biological children and just over $2 \%$ had step children. The percentage of households with both adopted and step children was effectively zero in all years. As reported in the second last column, the share of adoptive households (households with at least one adopted child) for whites fluctuated between $0.3 \%$ and $0.9 \%$ in 1880-1930 without time trends, while that for blacks increased from $1.1 \%$ to $2.3 \%$ except for a drop in 1920. Most interestingly, as reported in the last column, within adoptive households, the percentage of households with adopted children only was higher in 1880-1930 ( $60-76 \%$ for both races) than in 2000 ( $51 \%$ for both races). To the extent that the absence of biological children in a married two-parent household is an indication of infertility, ${ }^{14}$ it suggests that infertility might have been an important motivation for adoption since the earlier decades. I explore this issue further in the regression analysis.

To capture not only extensive but also an intensive margin, Table 4 reports the distribution of adoptive households by the number of adopted children in the household. Households are again restricted to married two-parent households. In 1880-1930, the average number of adopted children in white adoptive households was 1.1 (with a slight increase from 1880 to 1930) where $99 \%$ of these households had just one or two adopted children. Among black adoptive households, the average was 1.2 (with no time trends) where $99 \%$ of these households had one to three adopted children. No households had more than 5 adopted children in 1880-1930. Despite the decline in fertility and a fewer number of biological children per household in 2000, the number of adopted children in adoptive households was higher in 2000 than in 1880-1930 for both races.

### 4.4. Age Distributions of Adopted Children and Adoptive Mothers, $1880-1930$ \& 2000

Although we do not observe the age of a child at adoption, we can make some inference from comparing the age of adopted children and their mothers. For instance, if most adoptions were infant adoptions by mothers of childbearing age (age 15-45), then we expect the age distribution of adopted children (or adoptive mothers) to be similar to those of biological children (or birth mothers). Figure 1 presents the distribution of children's age by child type and by race. Again, the sample is restricted to children under age 18 in married two-parent households. Since the distributions do not differ much across years, I pool the 1880-1930 data (in the left panel) and compare against the 2000 data (in the right panel). In 1880-1930, for both races, the age distributions of biological children are close to linear

[^8]with a negative slope that primarily reflects a long-run trend in declining fertility. By contrast, the age distributions of adopted children in 1880-1930 exhibit an inverse U-shape that peaks at around age 10. Since the inverse U-shape pattern is seen in each census year and even in 2000 to some extent, it cannot be attributed to long-run trends in adoption. Instead it likely indicates that adoption took place at a steady rate from age 0 up to age 10 and stopped thereafter. By contrast, the age distributions of step children in all years increased monotonically with age, as children were selected into this category with their mother's remarriage perhaps independent of children's age.

Although not reported, I also compare the distributions of children's mother's age by child type in 1880-1930 and 2000. The age distributions of biological mothers and step mothers are very similar in 1880-1930 with a peak at around age 36 . This is consistent with the fact that, by our definition, step mothers were indeed biological mothers of the children who later remarried. The age distribution of adoptive mothers, by contrast, has a later peak (at around age 40) and a thicker and longer right-hand tail. In fact, as much as $25 \%$ of adopted children in 1880-1930 had mothers older than age 50. In 2000, the corresponding figure was about $15 \%$.

Perhaps most informative, Figure 2 presents the distribution of the age difference between a child and his or her mother by child type and by race in 1880-1930 and in 2000. While the age difference between biological or step children and their mothers were mostly (and naturally) confined to 15 to 50 years, the age gap between adopted children and their mothers ranged from 4 years to 70 years and beyond in 1880-1930. The age gap of 4-14 years implies the adoption of higher age children that is more consistent with "pragmatic" adoption. It is important to note that this portion completely disappears in 2000. [Also report the distribution of the age difference between the child and household head by child type including foster children here.] By contrast, the age gap of 50 years and above signals adoption by older couples, some of them were probably the grandparents of adopted children, that may be more consistent with "altruistic" adoption. In 2000, the distribution of the age gap between adopted children and their mothers for whites is not single-peaked, due likely to the presence of adopted stepchildren whose distribution is very different from the rest of adopted children. We can use Asian adopted children as a control group, as they consisted primarily of unrelated adoption with few related or stepparent adoption. As shown in the bottom right-hand panel, the age gaps between Asian adopted children and their mothers are largely confined to 20-50 years. This indicates that in "sentimental" adoption, mothers tend to adopt a child at childbearing age.

### 4.5. Characteristics of Adopted Children and Adoptive Parents, 1880-1930 \& 2000

In Tables 5-8, for selected census years, 1880, 1910, 1930, and 2000, I present demographic and socioeconomic characteristics of adopted children and their parents and compare their means against
those of biological children. For comparison, I also report the results for step children. The sample is restricted to white and black children under age 18 living in married two-parent households in 18801930, and white, black, and Asian children in 2000. The number of observations is also reported in the tables.

First, I discuss the results for white children. Compared to biological children, throughout 1880-1930, white adopted children were more likely to be female, were almost always the same race with their parents (i.e., little interracial adoption), were older, had much older parents, had substantially fewer number of biological siblings (i.e., biological children under age 18 in the same household), were more likely to be foreign born, and were twice as likely to be born out of state if native. What is more, a large fraction of white adopted children had a different surname from their parents. Because adoptive parents would typically change the child's surname to their surname upon legal adoption, different surnames likely indicate informal adoption or adoption at higher age. ${ }^{15}$ In terms of socioeconomic characteristics, compared to biological fathers, white adoptive fathers were less likely to work (due mainly to their higher age), more likely to be a professional, more likely to employ domestic servants at home, much more likely to own a house, more likely to be a farmer, and much less likely to live in a metropolitan area. [Although the descriptive statistics suggest that white adoptive households were better off than biological households, as shown in the later analysis, once father's age and other factors are controlled, such observation does not hold.]

There are some notable time trends. First, the difference in the average ages of adoptive and biological children among whites fell from 1880 to 1930, approaching the age difference of 1.1 in 2000. This may indicate a decline in children's age at adoption. Second, consistent with the historical literature, white adoptive fathers were no more likely to be a farmer than biological fathers towards the end of the period, but were much more likely to be a professional by 1930. The percentage of adopted children with different surname from their parents declined from $53 \%$ to $24 \%$ in $1880-1930$, likely indicating the rise in formal adoption.

With respect to children's education, we have three measures, literacy (i.e., can read and write), school attendance, and work status (i.e., have a regular occupation or not), available for children of age 10 and above. Due to small sample sizes, however, a difference between adoptive and biological children is not statistically significant in most cases. Nevertheless, it is worth noting that, among white children of age 10-15, their literacy rate increased from $90 \%$ to $99 \%$, school attendance rose from $70 \%$ to over $90 \%$, and labor force participation rate declined from $15 \%$ to $4 \%$ from 1880 to 1930.

[^9]Turning to black adopted children, some of their characteristics were similar to those of white adopted children in 1880-1930: compared to biological children, they were more likely to be female, were older, had substantially older parents, had fewer number of biological siblings, were more likely to be born out of state, and had an even higher percentage of children with a different surname from their parents. In terms of socioeconomic characteristics, there were some differences: compared to biological fathers, black adoptive fathers were less likely to be a farmer in 1880, but were more likely to be a farmer by 1930. They were more likely to own a house, like white adoptive parents, but more likely to live in a metropolitan area. The percentage of adopted children with a different surname from their parents declined from $65 \%$ to $37 \%$ in 1880-1930, showing similar trends. In terms of children's education, due to even smaller sample sizes, comparisons between adoptive and biological children are inconclusive. Nonetheless, black children in general experienced major advances as their literacy rate rose from $50 \%$ to $88 \%$ and school attendance from less than $30 \%$ to $88 \%$, while their labor force participation rate declined from over $40 \%$ to less than $20 \%$ between 1880 and 1930.

Finally, a comparison of adopted children and step children provides useful information. First, although only available in 1910, the number of mother's marriages shows that adoptive mothers were married only 1.17 times on average compared to 1.94 times for mothers of step children, further confirming that adopted children in 1880-1930 include only a limited number of adopted stepchildren. Second, by almost every socioeconomic measure, unlike adoptive households, step households were considerably worse off compared to biological households: stepparents were less likely to have a professional occupation, less likely to own a house, less likely to employ domestic servants, and less likely to be literate. This may be consistent with the fact that households were selected into step households by a death of previous household head and a subsequent decision of remarry to support a family. Furthermore, step children were less likely to be literate, less likely to attend school, and more likely to work, compared to biological children. Although this is likely driven by the fact that step children might have grown up in a less privileged household and were also substantially older, it may also indicate lower parental investment in step children.

## 5. Determinants of the Demand for Adoption: Theoretical Framework

The descriptive statistics shows that adopted children and adoptive parents were systematically and consistently different from their biological (and step) counterparts in 1880-1930. Except for some notable trends, there was no dramatic change in the characteristics of adopted children or adoptive parents between 1880 and 1930, however. In fact, many of the characteristics of adoptive households found in 1880-1930 are qualitatively similar to those in 2000. Did adoption evolve from "altruistic" and "pragmatic" adoption to "sentimental" adoption as the literature suggests? Was sentimental adoption a
dominant form as early as in 1880? One of the major challenges is to differentiate the three distinct motivations for adoption in the data. Before proceeding to more rigorous empirical analysis of the determinants of the demand for adoption, I develop a simple theoretical framework.

To formalize historical insights, consider an extension of the economic model of fertility (Becker $(1960,1965))$ in which a household can produce a child not only through birth but also through adoption. In this framework, a household determines the numbers of biological and adopted children by maximizing their lifetime utility, defined over children and a composite consumption good, given a time budget constraint. Note that, for adopted children, a household can also choose their age at adoption, $x$, and sex, $y$, at little cost. ${ }^{16}$ A household has imperfect control over producing biological children with an exogenous level of fecundity, $\gamma$. Children are assumed to be a source of satisfaction for parents for two separate reasons. First, parents derive sentimental value, $S$, from each child through experiencing parenthood and emotional bonding. Second, parents derive labor value, $L$, from each child's (immediate or future) contribution to market or household production. Parents also incur time cost, $C$, from bearing and rearing a child. Parents choose to allocate their times between market production and home production given their market wages and non-labor income.

Suppose that a child joins a household at age $x$ (for biological children, $x$ is always 0 ). Sentimental value, $S(x, y)$, is assumed to be decreasing in age $x$, and higher if sex $y$ is female. Furthermore, for given age and sex, I assume that parents derive greater sentimental value from biological children than adopted children: $S^{B}(x, y)=S^{4}(x, y)+\alpha$. The parameter $\alpha$ captures parental tastes for birth children over adopted children due, for example, to genetic concerns, which partially reflects social stigma attached to adoption. By contrast, labor value, $L(x, y)$, is assumed to be increasing in age and greater if a child is male. [This latter assumption is problematic if girls can be more productive in home production even if their market wages are lower.] For given age and sex, I assume that biological and adopted children are equally valuable in terms of their labor: $L^{B}(x, y)=L^{A}(x, y)$. Finally, I assume that the cost of raising children, $C(x, y)$, is decreasing in age $x$, as younger children demands higher parental attention, but invariant in sex $y$. The cost of raising an adopted newborn is assumed to be lower than the cost of raising a biological newborn because adoptive mothers don't have to bear a child: $C^{A}(0, y)<C^{B}(0, y)$. Therefore, the time cost for having a biological child is always higher than that for an adopted child. The values of $S(x, y), L(x, y), \alpha$ and $\gamma$, are assumed to vary across households depending on demographic and socioeconomic characteristics of parents.

[^10]Although simple, the model captures the economic logic of pragmatic and sentimental adoptions. On one hand, for couples who have high appreciation of children's labor value relative to sentimental value, they may strictly prefer adoption due to its lower time cost and adopt older children (pragmatic adoption). On the other hand, those couples who derive utility primarily from sentimental value and have high $\alpha$, they would not adopt children as long as they can produce their own biological children. When faced with low fecundity $\gamma$, however, some of them choose to adopt an infant and raise the child as their own (sentimental adoption), while others choose not to have any children.

Historical observations, however, suggest the third major motive for adoption not capture in the above model, i.e., altruism. Unlike pragmatic or sentimental adoption that is driven by parental demand and whose primary beneficiaries are parents, under altruistic adoption, couples adopt to help children whose biological parents fell on hard times. Altruistic adoption is hence supply-driven, and its primary beneficiaries are children. Altruistic adoption may be more common among extended families (i.e., related adoption) as adoptive parents more readily internalize the utility of extended family members, but it can occur between unrelated individuals if adoptive parents internalize the utility of adopted children.

In terms of testable predictions, we should expect that the age difference between the child and mother is smaller under pragmatic adoption and greater under altruistic adoption than under sentimental adoption. Adopted children are more likely to be male under pragmatic adoption (assuming that boys have higher labor value) and more likely to be female under sentimental adoption, while it can be either under altruistic adoption. Adopted children are more likely to be adopted legally under sentimental adoption and share the same surname with the parents (to be raised "as their own") than under pragmatic or altruistic adoption. As biological and adopted children are substitutes in both sentimental and pragmatic adoption, we expect the number of biological children in the household to be negatively correlated with the likelihood of both types of adoption. Because infertility is one of its key drivers, sentimental adoption should be strongly associated with having no biological children. By contrast, the presence of biological children should not reduce the likelihood of altruistic adoption or may even increase its likelihood.

Furthermore, we expect pragmatic adoption to be positively associated with factors that raise children's labor value relative to sentimental value. Farming is an important proxy in the following analysis because not only children are valued in farm labor but also child labor laws were not enforced in the agricultural sector. Another important factor is the presence of domestic employees (i.e., servant, housekeeper, maid, cook, and nurse) in the household. As these employees provide labor to home production, they should reduce children's labor value, particularly for girls, and thus are substitutes for
pragmatic adoption. By the same logic, working mother would increase the labor value of girls and thus the demand for pragmatic adoption for girls.

We expect sentimental adoption to be positively correlated with factors that reduce parental premium $\alpha$ on biological children over adopted children. Arguably, urban couples with higher education or higher socio-economic status are more "open minded" and thus have greater appreciation of children's sentimental value and lower $\alpha$. If this is the case, we expect literacy (the only available proxy for education), prestigious occupations (e.g., managerial and professional), urban residence, and household wealth (proxied by the presence of domestic employees and house ownership) to be positively correlated with sentimental adoption and negatively correlated with pragmatic adoption.

## 6. Determinants of the Demand for Adoption: Empirical Analysis

### 6.1. Logit for Propensity to Adopt, 1880-1930

Using the pooled 1880-1930 sample of married two-parent households with children under age 18, I estimate the propensity of a household to adopt a child in several specifications. The results are reported separately for white households (see Table 9) and for black households (see Table 10). The dependent variable is an indicator variable that takes 1 if a household has at least one adopted child and 0 otherwise. The numbers reported in the tables are marginal effects evaluated at mean values. ${ }^{17}$ All marginal effects are expressed in percentage point. In a baseline model in column (1), I include a set of basic household characteristics, year fixed effects, and region fixed effects. In column (2), I repeat the same specification but restrict the sample to households with mother of age 50 and below. In an extended model in column (3), I replace a socioeconomic index by occupational categories and include division fixed effects. Column (4) repeats the same specification with the restriction on mother's age. In column (5), as a proxy for household wealth, I add house ownership to the baseline model, but drop all observations in 1880 for which this variable is unavailable.

To measure a degree of substitution between biological and adopted children, in columns (1)(5), I include both the indicator variable for the presence of biological children (under age 18) and the total number of biological children (under age 18) in the household. To interpret these variables as a proxy for fertility, however, has several problems, even after controlling for mother's age. First, for older adoptive mothers who may have grown-up biological children, these variables would systematically underreport their total fertility. Second, the number of biological children is endogenous to adoption: the fewer number of biological children can be a result, rather than a cause, of adoption (especially for pragmatic adoption). Third, for sentimental adoption, anticipated (as opposed to

[^11]realized) fertility (e.g., difficulty in conceiving in the first two years of marriage) should matter. To address these issues, I compute two additional measures of fertility. In column (6), I use the number of biological children (under age 18) who are older than the first adopted child in the household. ${ }^{18}$ Because the age of adoption can be higher than 0 , this variable provides an upper bound estimate of the number of biological children prior to adoption. In column (7), to capture the fertility of mother at an early childbearing age, I use the number of biological children when mother was age 30 and restrict the sample to households with mother of age 30-40.

The results are fairly robust across all specifications. Main findings for white households are as follows. (1) The presence of biological child has a very large negative effect on the propensity to adopt, while having an additional biological child has a negative but much smaller effect. (2) The presence of domestic employees (e.g., servant, housekeeper, maid) and other non-domestic employees (unspecified) in the household is positively associated with adoption. (3) Living in a metropolitan or urban area is negatively associated with the likelihood of adoption. (4) Literacy of father has a negative effect, while literacy of mother has a positive effect on adoption. (5) Higher socioeconomic index (Duncan's index based on occupational income and prestige) of father and mother are both negatively associated with the propensity to adopt. House ownership is also negatively correlated with adoption. (6) Working father (i.e., having a regular occupation) and working mother are both positively associated with adoption. (7) Farmer fathers are more likely to adopt, but professional fathers are less likely to adopt. In terms of parental motivations to adopt, the results are mixed. The findings (1) and (2) are consistent with sentimental adoption and inconsistent with pragmatic adoption, while the findings (3), (5), (6), and (7) support pragmatic adoption and reject sentimental adoption. The finding (1) is inconsistent with altruistic adoption.

For black households, main results are as follows. (1) Again, the presence of biological child has a disproportionately large and negative effect on the propensity to adopt. (2) The presence of domestic employees has no effect, but the presence of non-domestic employees has a large positive effect on adoption. (3) Living in a metropolitan (but not urban) area is negatively associated with the likelihood of adoption. (4) Literacy of father has a negative effect on adoption. (5) In contrast to white households, higher socioeconomic index of father is positively associated with the propensity to adopt. The effect of house ownership, however, is negative. (6) Working father is positively associated with adoption, while working mother is negatively associated. (7) Both farmer fathers and farmer mothers have large and positive effects on adoption. (8) Professional fathers are more likely to adopt, while professional mothers are less likely to adopt. Again, the results are mixed. The findings (1), (6), and (8) are consistent with sentimental adoption and inconsistent with pragmatic adoption, while the findings

[^12](3), (4), and (7) are consistent with pragmatic adoption and inconsistent with sentimental adoption. In other words, the empirical evidence seems to indicate that all three types of adoption coexisted in 18801930 for both races. In the following analysis, I look into across-time variations and variations in the characteristics of adopted children to better identify different types of adoption.

### 6.2. Logit for Propensity to Adopt, 1880-1900 vs. 1910-1930

To see whether the determinants for the demand for adoption changed over time, I divide the data into two periods, 1880-1900 and 1910-1930, and run the same logit regressions as in the previous section. [Results to be added.]

### 6.3. Multinomial Logit for Propensity to Adopt, 1880-1930

To investigate the determinants of adoption demand further, I classify adoptive households by the characteristics of children and estimate the propensity to adopt using multinomial logit. I consider three models. In the first model, a household chooses from three outcomes: (a) no adoption, (b) adoption of a boy, and (c) adoption of a girl. Because some households have multiple adopted children, I use the sex of the first adopted child to classify the adoptive households into the outcomes (b) and (c). According to the theoretical predictions, we should observe more pragmatic adoption in the outcome (b) and more sentimental adoption in the outcome (c), while altruistic adoption is equally likely in (b) and (c). The purpose of this analysis is to see whether the characteristics of households that make the outcome (b) more likely than the outcome (c) are consistent with the predictions of pragmatic adoption. I report the results for two specifications. In column (1), in addition to a basic set of variables, I include the numbers of male and female biological children older than the first adopted child. In column (2), I repeat the same specification, but restrict the sample to households with mother of age 50 and below. The results for white households are reported in Table 11, and the results for black households are reported in Table 12. The numbers in the tables are expressed in the ratio of relative risks (RRR), which is a relative probability of choosing a given outcome over the base outcome (which is defined to be "no adoption"). When RRR for variables $x$ is greater than 1 , it means that $x$ increases the relative likelihood of a given outcome over the base outcome. [Discuss main findings.]

In the second model, I consider the choice of household among three outcomes: (a) no adoption, (b) adoption only and no biological children, and (c) adoption in the presence of biological children. The last category consists of households that have both adopted children and biological children who are older than the first adopted child. According to the theoretical predictions, the outcome (b) should consist largely of sentimental adoption, while the outcome (c) should consist
largely of pragmatic and altruistic adoption with minimum sentimental adoption. I report the results for two specifications. In column (1), I include a basic set of variables and, in column (2), I restrict the sample by the age of mother. The results for white households are reported in Table 13, and the results for black households are reported in Table 14. [Discuss main findings.]

In the third model, I assume that a household have a choice over three outcomes: (a) no adoption, (b) formal adoption, and (c) informal adoption. Because I don't observe formal adoption in the data, I use the same surname as a proxy for formal (i.e., legal) adoption. Namely, I classify adoptive households that have at least one adopted child who shares the same surname with both parents into the category (b) and the rest of adoptive households into the category (c). According to the theoretical predictions, the outcome (b) should consist primarily of sentimental adoption, while the outcome (c) should contain both pragmatic and altruistic adoption. I report the results for two specifications. In column (1), I include a basic set of variables and the number of biological children older than the first adopted child. In column (2), I restrict the age of mother. The results for white households are reported in Table 15, and the results for black households are reported in Table 16. [Discuss main findings.]

## 7. Conclusion

Notes:
(1) Children are defined as any person under age 18 residing in a household whose relationship to a household head is reported as "child," including biological,
adopted, and step children. Foster children are reported under a separate category as part of "non-relatives" but included in children in this table.
(2) Alaska, Hawaii, and Oversea military installations are excluded to ensure consistency across all years.
(3) Children with ambiguously identified mother or father are excluded.
(4) N/A: estimates are not available due to a small sample size.

Source: Same as Table 1.
(1) Children are defined as any person under age 18 residing in a household whose relationship to a household head is reported as "child," including biological, adopted and step children.

Foster children are reported under a separate category as part of "non-relatives" but included in children in this table.
(2) Alaska, Hawaii, and Oversea military installations are excluded to ensure consistency across all years.
(3) Children with ambiguously identified mother or father are excluded.
(4) Significantly different from \% for biological children of the same race at $1 \%$ level ${ }^{* * *}$, at $5 \%$ level ${ }^{* *}$, at $10 \%$ level ${ }^{*}$, using robust standard errors.

## Source: Same as Table 1.

Notes:
(1) Children are defined as any person under age 18 residing in a household whose relationship to a household head is reported as "child," including biological, adopted, and step children.
(2) Alaska, Hawaii, and Oversea military installations are excluded to ensure consistency across all years.
(3) Only married two-parent households with at least one adopted child are included.
(4) The race of household is defined by the race of the household head. Only white households and black households are included.

Source: IPUMS 2000 1\% Sample.
Source: IPUMS $20001 \%$ Sample.
(1) Children are defined as any person under age 18 residing in a household whose relationship to a household head is reported as "child," including biological, adopted, and step children.
(2) Alaska, Hawaii, and Oversea military installations are excluded to ensure consistency across all years.
(3) Only children in a household with two married parents are included. Children with ambiguously identified mother or father are excluded.
(4) Significantly different from the mean of biological children of the same race at $10 \%$ level ${ }^{*}$; at $5 \%$ level ${ }^{* *}$; at $1 \%$ level ***

*** $p<0.01$, ** $p<0.05$, * $p<0.1$; robust t-statistics are reported in brackets.
Marginal effect for age is computed at mean age and includes linear and quadratic terms
I[.] is an indicator variable that takes 1 if condition [.] holds. "SEI/10" is Duncan's socioeconomic index normalized to take value 0-10.
In occupation indicator variables, the omitted category is "unskilled."

Base outcome is no adoption. The outcome "adopt, same surname" is defined as having at least one adopted child who has the same surname with both parents.
Statistical significance for RRR is based on the null: RRR=1.
*** $p<0.001$, ${ }^{* *} p<0.01$, * $p<0.05$; robust $t$-statistics are reported in brackets.
RRR for age is computed at mean age and includes linear and quadratic terms.
I[.] is an indicator variable that takes 1 if condition [.] holds.
In occupation indicator variables, the omitted category is "unskilled."
"Test" columns test the null: RRR(outcome1)=RRR(outcome2); ^^^ $p<0.01, \wedge^{\wedge} p<0.05, \wedge p<0.1$.

Figure 1: Distribution of the Age of Children by Type and Race of Children, 1880-1930 \& 2000

Figure 2: Distribution of the Age Difference between Child \& Mother by Type and Race of Children, 1880-1930 \& 2000

[^0]:    * This is a work in progress: comments are welcome (email address: chiaki@northwestern.edu).

    I thank Ka Hei Tse and Tuan Hwee Sng for their wonderful research assistance. I am also grateful to Joe Ferrie and Joel Mokyr for their advice and encouragement.

[^1]:    ${ }^{1}$ The orphan train movement declined after 1899 as more states chose to restrict inter-state adoption (Pick (1924)).

[^2]:    ${ }^{2}$ A typical adoption form set the terms and conditions for adopting a boy as follows: "To care for him in sickness and health, to send him to school during the entire free school year until he reaches the age of 14 years, and thereafter during the winter months at least, until he reaches the age of 16 years; also to have him attend Church and Sunday School when convenient, and to retain him as a member of my family until he reaches the age of 17 years, and thereafter for the final year, until he is 18 years old, to pay the boy monthly wages in addition to his maintenance [...]" (New York Children's Aid Society's adoption form, undated, obtained from URL: http://www.orphantraindepot.com/CASForm.html).
    ${ }^{3}$ Legal cost for adoption was $\$ 10-25$ in 1904, equivalent to $\$ 200-500$ in 2000 using CPI or $\$ 800-2,000$ using unskilled wage.
    ${ }^{4}$ Although infant formula was first commercially introduced in the 1870 s , its quality was far inferior to maternal milk. An important breakthrough came in the early 1920s, resulting in infant formula that matched maternal milk in nutritional content and was widely recommended by pediatricians (Albanesi and Olivetti (2007), p.10).

[^3]:    ${ }^{5}$ At the same time, adoption agencies carefully screened children and excluded children with disability or questionable heredity as "unadoptable" (Berebitsky (2000), p.134).

[^4]:    ${ }^{6}$ See U.S. Census Bureau (2003) for a summary report for adopted children in the 2000 census. After 2000, the census ceased to distinguish adopted children from biological children.
    ${ }^{7}$ In the following analysis, I use IPUMS $18805 \%$ sample (with minority oversamples), $19002.5 \%$ sample (with minority oversamples), $19101.4 \%$ sample (with minority oversamples), $19201 \%$ national random sample, and $19301 \%$ national random sample.

[^5]:    ${ }^{8}$ Foster children refer to children who are temporarily cared for by foster parents while their birth parents are unable to perform parental duties due to financial, medical, or emotional reasons. Unlike adoptive parents, foster parents do not assume parental rights. Historically, however, these two concepts were not well differentiated.
    ${ }^{9}$ Note, however, that our definition of adopted children excludes those who are reported as a household head's "adopted brother (or sister)," "adopted nephew (or niece)," and "adopted grandson (or granddaughter)" even if they are under age 18.

[^6]:    ${ }^{10}$ Among Asian adopted children in $2000,73.0 \%$ had a white household head and $26.3 \%$ had an Asian household head.

[^7]:    ${ }^{11}$ In 1880-1930, roughly $80 \%$ of separated, divorced, or widowed adoptive parents were female, but surprisingly, about $50 \%$ of the never-married adoptive parents were male.
    ${ }^{12}$ A sizable share of step children in 2000 lived with a never-married household head, however: these were mostly biological children of an unmarried partner of the household head reported as "stepchildren" (U.S. Census Bureau (2003), p.3).

[^8]:    ${ }^{13}$ In 1880-1930, because both inter-racial marriage and inter-racial adoption were almost nonexistent, the race of a household head and the race of his spouse or child were almost always the same. In 2000, this was not the case.
    ${ }^{14}$ Having no biological children under age 18 does not imply having no biological children of any age.

[^9]:    ${ }^{15}$ Almost all married couples shared the same surname in 1880-1930. Note that informal related adoption (i.e., adoption of related children in a paternal line) may also result in adopted children having the same surname with their parents.

[^10]:    ${ }^{16}$ This assumption is appropriate for the 1880-1930 period when an excess supply of adoptable children allowed adoptive parents to select children according to their preferences with no adoption fee and little waiting time. The assumption is less valid in 2000 when, under a large excess demand, adoptable children were allocated by adoption agencies, often according to their preferences, and adoptive parents incurred substantial financial and time costs in adopting a child (Bernal et al. (2007)).

[^11]:    ${ }^{17}$ For indicator variables, marginal effects are for discrete change from 0 to 1 evaluated also at sample means.

[^12]:    ${ }^{18}$ If there is no adopted child, then this variable is equal to the number of all biological children.

[^13]:    *** $p<0.01,{ }^{* *} p<0.05, * p<0.1$; robust $t$-statistics are reported in brackets.
